# **Topic 5**

#### Hazards

## The concept of hazard in a geographical context

Modern ideas see hazards as the outcome of the interaction between human use systems (like land use) and natural event systems (the natural environmental processes which give rise to hazards). This interaction promotes actual hazard events which we perceive and then respond to. The way we react can in turn modify the human use system (for example by changing land use), the natural events system (for example by changing the magnitude/frequency relationship for river flooding), or both.

The Park model of human responses to a hazard sketches the phases following a hazard event.

#### Plate tectonics

Plate tectonics is the theory that the Earth's outer shell (the crust or lithosphere) is divided into several plates that glide over the rocky inner layer (the mantle) above the core. The plates act like a hard and rigid shell compared to the mantle. Developed from the 1950s through to the 1970s, plate tectonics is the modern version of the theory of continental drift, a theory first proposed by Alfred Wegener in 1912.

The crust of the Earth is divided into rigid plates that vary in shape and size and move relative to one another over the globe. There are nine major plates: the Eurasian, African, South American, North American, Nazca, Antarctic, Pacific, Juan De Fuca and Indian–Australian.

Most of the edges of these plates are geologically active.

		<u>/</u>		<mark></mark>

Constructive plate boundaries occur where plates move away from each other and fresh magma wells up to fill the gap. This creates new crust as it cools and solidifies. Figure 5.3 shows how these boundaries evolve from a bulge in the crust underneath upwelling magma to a continental rift valley (e.g. the Great African Rift Valley), to a linear sea (e.g. the Red Sea) and finally to an ocean.

### Volcanic hazards

A volcanic hazard refers to any potentially dangerous volcanic process (e.g. lava flows, pyroclastic flows, ash). A volcanic risk is any potential loss or damage as a

result of the volcanic hazard that might be incurred by persons, property etc. or which negatively impacts the productive capacity/sustainability of a population.

(6) Choose two of the volcanic hazards shown in Figure 5.8 and, using examples, explain the cause and describe the effects of the named hazards. (AO1, AO2) Figure 5.8 A simplified diagram showing some of the most common forms of volcanic hazard Eruption cloud Prevailing wind Ash Eruption column (tephra) fall Pyroclastic flow Acid rain Bombs Landslide Lava dome (debris Lava dome collapse avalanche) (mud/debris flow) **Fumaroles** Ground water Pyroclastic flow Crack Lava flow Magma

#### Seismic hazards

Most of the seismic hazards to people come from human-made structures and the shaking they receive from earthquakes. The real dangers to people are being crushed in a collapsing building, drowning in a flood caused by a broken dam or levee, getting buried under a landslide, or being burned in a fire.

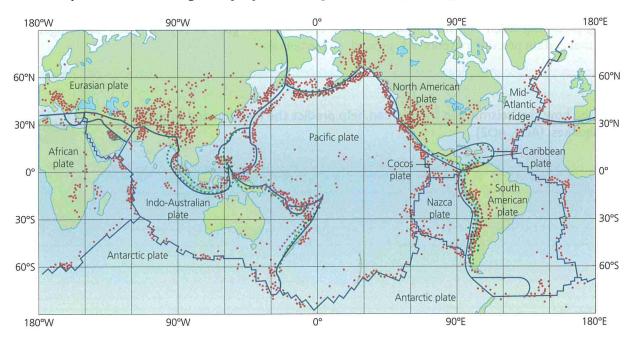

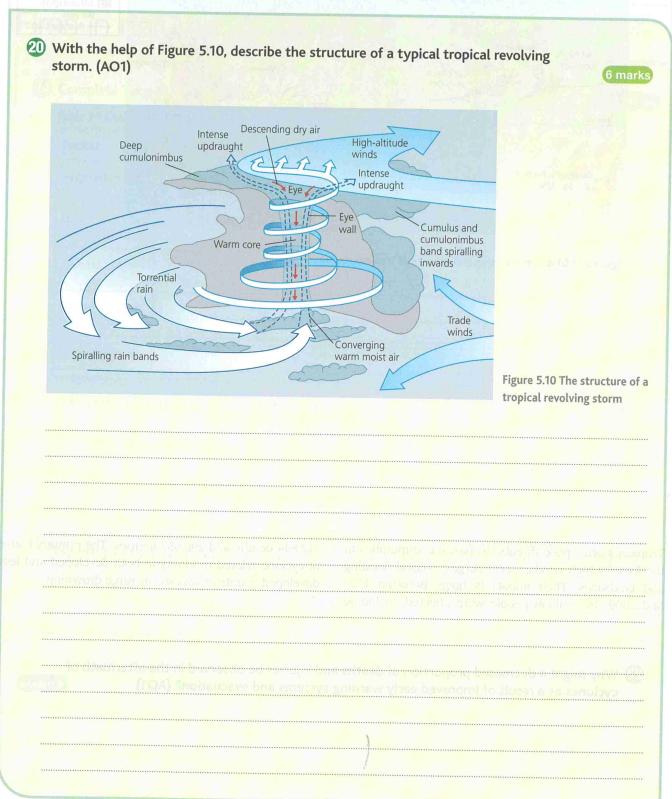

Figure 5.9 Earthquake locations for events between 1965 and 1995. The red dots are shallow earthquakes, the green are intermediate depth, and the purple are deep

#### Storm hazards

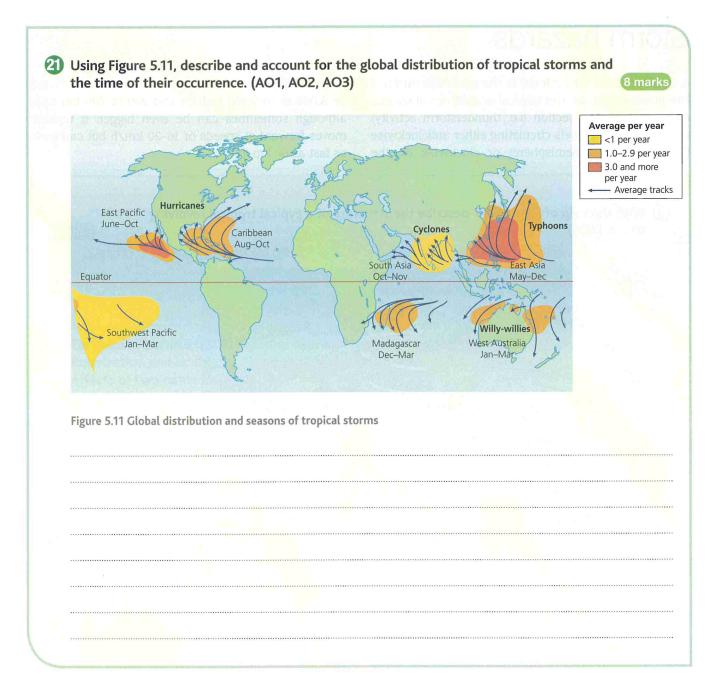

A tropical storm (or cyclone) is the generic term for a low-pressure system over tropical or subtropical waters, with organised convection (i.e. thunderstorm activity) and winds at low levels circulating either anticlockwise (in the northern hemisphere) or clockwise (in the

southern hemisphere). The whole storm system may be 8,000 m to 9,500 m high and 200 to 700 km wide, although sometimes can be even bigger. It typically moves forward at speeds of 16–20 km/h but can travel as fast as 60 km/h.

Tropical storms require a certain set of environmental conditions in order to develop. Once they have been triggered, they move westwards and northwards

(southwards in the southern hemisphere) until they come under the influence of westerly winds. They then start to reverse their direction into an easterly path.

Tropical storms pose threats to coastal communities in the form of high winds, storm surges, coastal flooding and landslides. Their impact is huge. Between 1980 and 2009, 466 million people were affected, including 412,644 deaths and 290,654 injuries. The primary cause of cyclone-related mortality in both developed and less developed countries was storm surge drowning.

Why might a decrease cyclones as a result of	ed proportion of deaths a improved early warning	and injuries be observe systems and evacuat	ed in the aftermath ion? (AO1)	of 4 mark

2 The United Nations office for Disaster Reduction has produced statistics regarding the number of natural disasters and the total costs of the damage incurred.

Table 5.2 shows the figures for the top ten countries with most disasters between 2005 and 2014.

Table 5.2

Country	Number of natural disasters	Rank	Total damage (\$ billion)	Rank	d	<b>d</b> <sup>2</sup>
China	286	1	265	2	-1	1
USA	212	2	443	1	+1	1
Philippines	181	3	16	7	-4	16
India	167	4	47	4	0	0
Indonesia	141	5	11	8	-3	9
Vietnam	73	6	7	9	-3	9
Afghanistan	72	7	0.16	10	*	
Mexico	64	8	26	5	3	9
Japan	62	9	239	3		
Pakistan	59	10	25	6	4	16

Calculate the Spearman's rank correlation coefficient for the two sets of data by completing Table 5.2 and using the formula:

$$R_s = 1 - \frac{6\sum d^2}{n^3 - n}$$

Where:

R<sub>s</sub> is the Spearman's rank correlation coefficient

n is the number of pairs of variables

 $\sum d^2$  is the sum of the differences in rank squared.

Critical values for Spearman's rank where n = 10:

	Significa	nce level
n	0.05	0.01
10	+/- 0.564	+/- 0.746

Complete Table 5.2 and interpret your Spearman's rank result using the critical values above. (AO3)
